

Map A – Present-day Antarctica showing ice cover

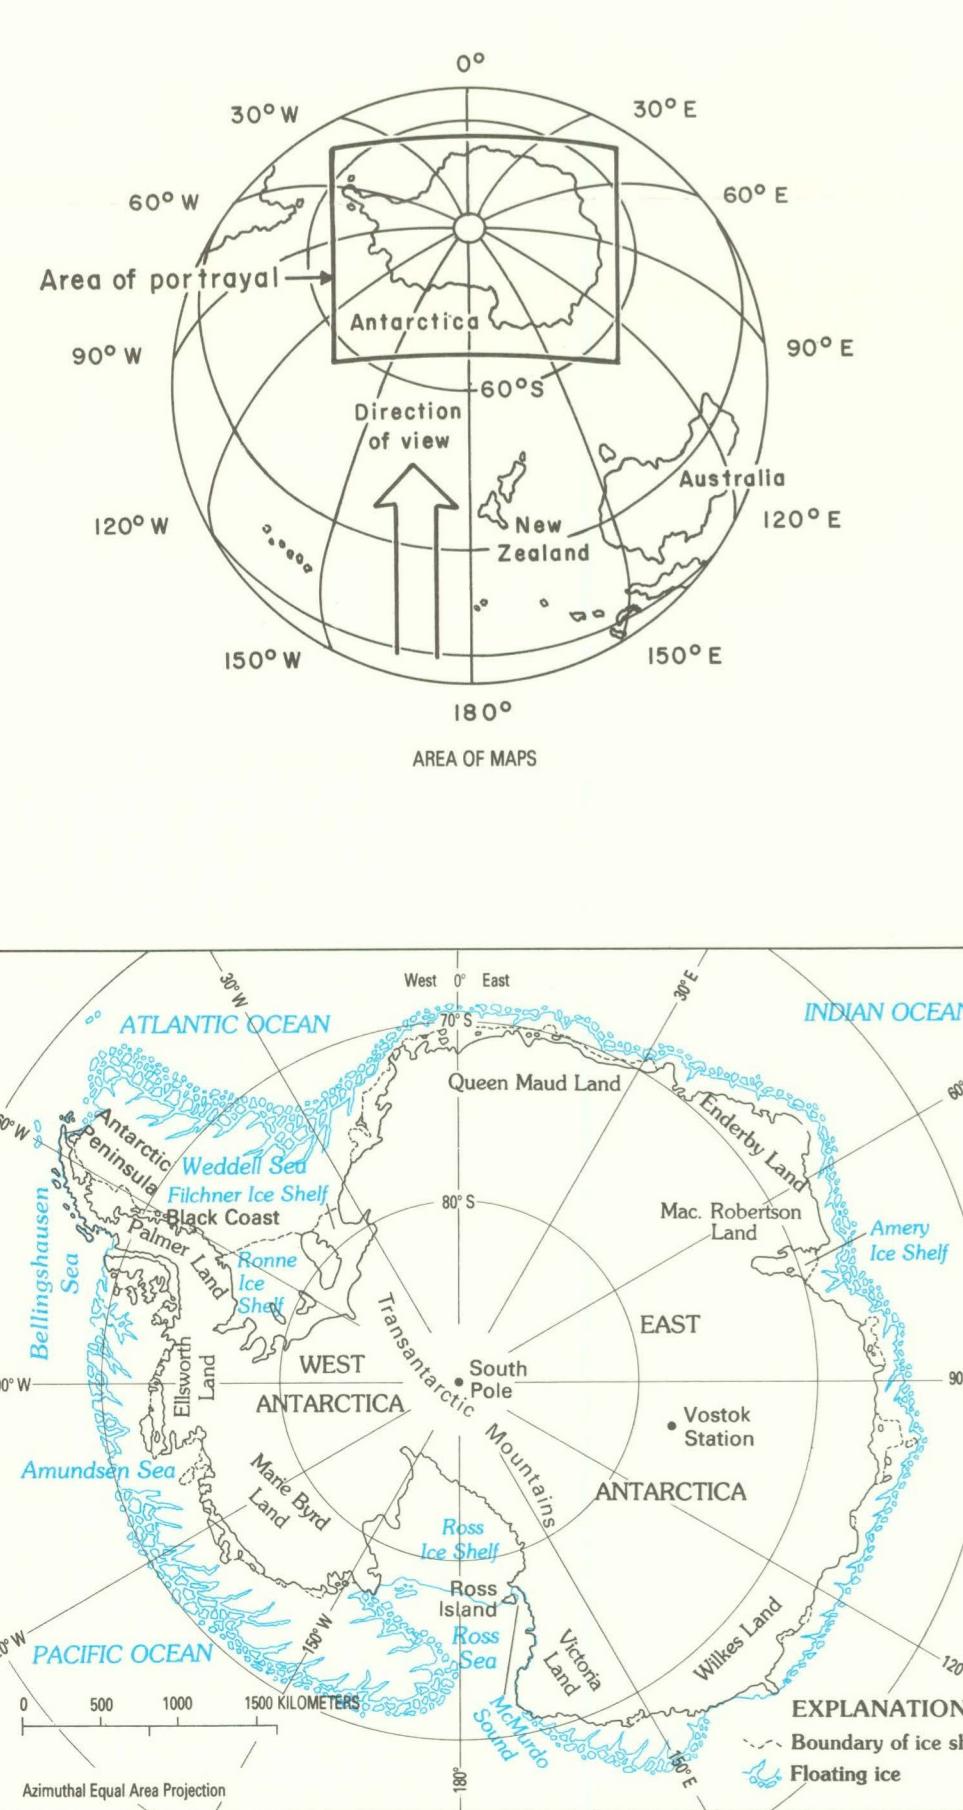

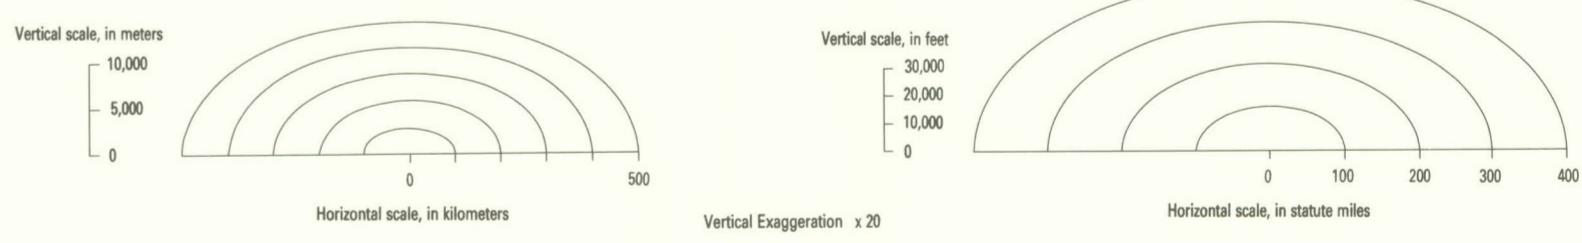

INTER-GEODIALOGIC SURVEY EDITION VA-1988
Manuscript approved for publication May 13, 1988

Map B – Antarctica after ice melt

Map C – Antarctica after isostatic rebound

INTRODUCTION

Antarctica, which is a name that means opposite of the Arctic, is a continent of about 13,918,000 km² (5,350,000 mi²) that surrounds the South Pole. An average elevation of about 2,500 m (8,000 ft) makes it by far the world's highest continent followed by Asia, about 900 m (3,000 ft). Except for the mountainous upwelling of the Transantarctic Mountains, the continent is a desert and is devoided, indicated by the Ross and Weddell Seas. The continent is divided into two areas by the Transantarctic Mountains: the larger area, called East Antarctica, lies mostly in the southern hemisphere, the smaller area, called West Antarctica, lies entirely in the northern hemisphere. These two areas are also sometimes called as greater and lesser Antarctica.

Home of the Blizzards are polar regions. Deserts in the true sense, because the water precipitation is very low, the wettest region averages less than 10 cm (4 in.) in water equivalence of snowfall. The precipitation is much greater, however, in coastal areas. Common blizzard winds (atmospheric winds draw cold, dense air masses from high pressure areas to low pressure areas) blow across the continent, with a recorded temperature of -69.2 °C (-88.6 °F) was measured at the Soviet Union's Vostok Station in interior East Antarctica (July 21, 1983). Other than abundant coastal seafords, few native plants and animals, such as algae, lichens, and insects, endure the harsh climate. Lovering and Preston (1979), Bonner and Walton (1985), Ford (1986), and Walton (1987) provide general descriptions of the continent and its geology and glaciology.

The Antarctic continent, known as Terra Australis by early explorers, was not sighted until 1820. Since the naming of Antarctica, a few other areas were charted by commercial whalers, sealers, and oceanic science explorations.

Interior regions south of the Ross Sea were visited or flown over in pioneering explorations of the early 1930's, but other areas of the continent remained little known except for the northern Antarctic Peninsula.

The mapping of Antarctica began primarily from the 1957-58 International Geophysical Year (IGY), a cooperative international effort to lead the first reconnaissance explorations of the entire continent and to the 1961 Antarctic Treaty, which has allowed widening scientific studies and mapping by many nations, including mapping by satellite in recent years.

As part of this international mapping endeavor, the U.S. Geological Survey (USGS) has produced more than 130 topographic maps at a variety of scales, including 1:250,000-scale maps of the entire Transantarctic Mountains, the Ellsworth Mountains, the Byrd Land area, and all the principal mountain areas of West Antarctica, except the Ellsworth Mountains and north half of the Antarctic Peninsula; 1:500,000-scale topographic maps of most of Wilkes Land; 1:500,000-scale topographic maps and maps of areas of Victoria Land near McMurdo Sound; satellite imagery maps at scales of 1:250,000 to 1:1,000,000 for the Ellsworth Mountains and the Victoria Land coast and McMurdo Sound region (U.S. Geological Survey, 1987). All major exposed mountain areas of Antarctica have been mapped and assigned some scale by many nations. The last large area of previously unvisited mountains, the central coast of Palmer Land (see index map), was studied in a cooperative geologic study by the British Antarctic Survey and USGS in the summer of 1986-87 (Walton and others, 1987).

The Transantarctic Mountains is one of the world's greatest mountain belts, dominant for all other ranges of the continent. Appropriately named, the range stretches more than 3,500 km (2,200 mi) across Antarctica from the southern Pacific shores of Victoria Land to the southern Atlantic coasts of the eastern Weddell Sea, nearing the South Pole. The Transantarctic Mountains, which in Eskimo means lonely peak) protruding through the ice. The two smaller maps portray the bedrock surface of the continent as it would look without ice cover, before and after isostatic rebound.

METHODS AND SOURCES

The oblique maps of Antarctica were prepared by isostigraph methods described in Alpha and others (1988). Map A, showing today's ice-covered continent, and map B, showing the bedrock surface without ice, are based principally on Drewry (1983) and are 1:10,000,000-scale contour maps. Map C, showing the bedrock surface adjusted for isostatic rebound after loss of the ice load, is based on Drewry (1983, sheet 6) 1:10,000,000-scale contour map. Additional data are from Behrendt and others (1974) for areas south of the Weddell Sea and the Canadian hydrographic surveys (Behrendt and others, 1986) and Drewry and Cooper (1987) for areas of the Ross Sea continental shelf. Alpha (1975) provides an oblique map of the Ross Sea continental shelf.

Alpha (1975) provides an oblique map of the Ross Sea continental shelf, which shows the principal physiographic features of the continent, such as the Transantarctic Mountains, Ellsworth Mountains, Antarctic Peninsula, and the Ross Ice Shelf. Moreover, the orientation of Antarctica, based on 0° as arbitrary north, is used here. Contour lines are projected from the hydrographic surveys to display a 20:1 vertical exaggeration. Distances scaled on the map vary with orientation, from a maximum in the east-west direction to a minimum in the north-south direction, as shown in the elliptical scales of the maps. Distances scaled on the map are the scale's zero point along a direction parallel to the mean orientation vector of the map.

The oblique maps were derived from the compiled contour profiles by using formalities to show physiographic interpretation of geomorphic features. Verticity of formalines shows steepness of slopes, varying from near vertical or vertical for steep slopes, such as on the Antarctic Peninsula, to nearly horizontal for vertical surfaces, such as on the Ross Sea continental shelf.

Geographic names used on the diagrams are primarily those approved by the United States Board on Geographic Names (Alberts, 1980, and supplements). Drewry (1983), however, uses many additional names, particularly for ice-covered areas of Wilkes Land and areas to the south.

ICE AND MOUNTAINS

Antarctica's highest mountain is in West Antarctica in the Ellsworth Mountains, where Vinson Massif (map A) reaches 5,140 m (16,860 ft). The Antarctic Peninsula, a southwest extension of the continent, is a lower, but still rugged mountain chain rising from sea level to a maximum of 2,600 m (8,500 ft) near Mount Jackson. Central low mountains and nunataks are scattered along the coast of East Antarctica, where the highest peaks reach 3,355 m (11,000 ft) near the Amery Ice Shelf (Prince Charles Mountains). Most of the land in East Antarctica is covered by the Queen Maud Land and Ellsworth Mountains. Isolates of Marie Byrd Land are depicted by five volcanic mountains, some of which reach elevations of 3,400 m (11,200 ft) or more.

Other ranges, such as the Gumboldt Subglacial Mountains (about 3,000 m (10,000 ft) high), lie below under the sheets of interior East Antarctica. Few traverses across the ice shelf to these mountains are known, but some remote-sensing data suggest that the mountain summits in places may actually reach or possibly even breach the ice surface (J.C. Behrendt, oral commun., 1987).

THE LAND BEHIND THE ICE

Without ice, Antarctica's continental outline would be much different from the present outline. If the earth's ice melted, sea level would rise some 80 m (260 ft). The sea would cover large areas of Antarctica, and the continent would appear as an island as shown in map B.

Glaciation in Antarctica began tens of millions of years ago when glaciators in the mountains built up and eventually covered the continent. Glaciers and ice shelves, icebergs, and the like, are currently exposed. Antartica peaks indicate that the ice shelves were thicker than they are today. The lithosphere was compressed by as much as 950 m (3,000 ft) under the thickest ice in East Antarctica (Drewry, 1983). Loss of the ice load by melting would eventually result in crustal collapse and erosion upward of land in a process of isostatic rebound. The oblique (vertical) latitudes tens of thousands of years for full land conversion. The oblique map (map C) illustrates isostatically adjusted bedrock surface (map C) shows not only how the continent might look long after ice removal but also how it looked prior to glaciation.

The ruggedness of the bedrock surface as shown on maps B and C is highly variable, ranging from subdued relief across large regions of East Antarctica and under the Ross and Weddell Seas to high relief in most areas of presently exposed mountains, as well as in central West Antarctica and areas of Victoria Land and the Transantarctic Mountains. The appearance of the topographic surface is probably due largely to spacing of data. Most areas shown in low relief have few seismic-reflection data points and few or unreliable radio-echo survey lines, whereas data are more abundant for areas of rugged relief (Drewry, 1983, sheet 3).

The Transantarctic Mountains consist chiefly of East Antarctica indented deeply by two principal marine basins: the Wilkes Subglacial Basin, and the Amery basin of Drewry (1983) near the present Amery Ice Shelf. Several small inland areas below sea level could be large freshwater lakes and inland seas, one of them, the Dry Valleys, is about 1,000 m (3,300 ft) deep.

The Ellsworth Mountains would become an island chain soon after the ice melted (map B) and would be connected by a ridge to the continent after isostatic uplift. Other areas of West Antarctica could be islands or seaways to the C. The Byrd Land and Black Coast areas of West Antarctica are bounded by the 1,000 m (6,500 ft) depth. The troughs over 1,500 m (5,000 ft) deep would include the Byrd Subglacial Basin and the Thiel trough of Drewry (1983) west of the Pensacola Mountains.

ACKNOWLEDGMENTS

Our indebtedness to all mappers of Antarctica from the early 1900's pioneering age to today's satellite era is immeasurable. We particularly acknowledge David A. Drewry, British Antarctic Survey (Cambridge), for his maps published in 1983. Alan K. Cooper, John C. Behrendt, and Baerbel K. Lucassen provided helpful discussions and comments on an earlier version of these oblique maps.
